1 Introduction

The Janitor is a service for an automated installation of runtime environments (RTEs) for grid computing elements. It is addressed transparently via the A-REX service for job submission but can also be used as a standalone tool.

1.1 Motivation

A major motivation for grid projects is to stimulate new communities to adopt the technology to start sharing their resources. From the current grid user’s viewpoint, the admission of users of a very different education will suddenly impose difficulties in the communication between site maintainers. One will not even understand the respective other side’s research aims. Hence, the proper installation of non-standard software (runtime environments, RTEs) is not guaranteed. And the available time for manual labour plus self-education is scarce.

A core problem remains to distribute a locally working solution, the Know-How, quickly across all contributing sites, i.e., without manual interference. Every scientific discipline has its respective own set of technologies for the distribution of work load. E.g. research in bioinformatics requires access to so many different tools and databases, that few sites, if any, install them all. Instead, the use of web services became a commodity, with all their intrinsic problems as there are bottlenecks and restrictions of repeated access. The EU project KnowARC∗ amongst other challenges with the here presented work extends the NorduGrid’s Advanced Research Connector (ARC) grid middleware [?] towards an infrastructure for the automated installation of software packages.

An automation of the software installation, referred to as dynamic Runtime Environments (dRTEs), seems the only approach to use the computational grid to its full potential. Components of workflows shall be spawned as jobs in a computational grid using dRTEs rather than accessing a web service at one particular machine that is shared amongst all users. The grid introduces an extra level of parallelism that web services cannot provide. The demands for short response times and the heterogeneous education of site-administrators on a grid demand an automatism for the installation of software and databases without manual interference [?].

1.2 Overview

This document first dedicates a chapter on how to set-up the Janitor locally. It is followed by a chapter that gives further instructions on how to use the Janitor with A-REX and/or without A-REX. Afterwards, in the third chapter, the maintenance of the program will be presented, which is basically covering the method how to prepare new dRTEs. Deeper insights on the design of the Janitor will be given by the forth chapter. The document ends with an outlook to anticipated future developments and opportunities.

Abbreviations

RTE –Runtime Environment
dRTE–dynamic Runtime Environment
RDF –Resource Description Framework (supporting the RTE Catalog)

∗http://www.knowarc.eu
I Introduction
2 Installation

The Janitor requires the two perl packages listed in table 2.1. To have the WebService interface for the Janitor, the packages listed in the table 2.2 need to be installed before the build process is. The Perl modules are available on CPAN and ship with all major Linux distributions.

Table 2.1: Required perl packages for Janitor. Log4perl is used for the internal logging of Janitor, while the Redland RDF library is used for accessing the catalogue of Runtime Environments.

<table>
<thead>
<tr>
<th>Package</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>liblog-log4perl-perl</td>
<td>Log4perl, a port of the log4j logging package</td>
</tr>
<tr>
<td>librdf-perl</td>
<td>Perl language bindings for the Redland RDF library</td>
</tr>
</tbody>
</table>

Table 2.2: Optional libraries for the Janitor. The library libperl-dev provides the required header files to link the WebService to the Perl interpreter.

<table>
<thead>
<tr>
<th>Package</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>libperl-dev</td>
<td>Perl library: development files</td>
</tr>
</tbody>
</table>

The Janitor will be installed by default along with ARC-NOX. Support for the dynamic REs can be completely disabled at compile time by using the configure flags ‘-disable-janitor-service’ for the complete janitor or ‘-disable-janitor-webservice’ to only disable the Janitor’s Web Service.

Furthermore it is recommended to install the ontology editor Protégé* in order to easily maintain the knowledge database of installable packages. At the time of writing, no Linux distribution is offering packages for this fine tool.

2.1 Configuration

The current version of the Janitor can be configured using the common file arc.conf. It is expected in the configuration directory etc. The Janitor is using the environment variable NORDUGRID_CONFIG to determine the location of the corresponding file. If that variable is not set, the default location /etc/arc.conf will be used. The configuration is assigned by the section [janitor]. Table 2.3 describes the available tags for Janitor’s configuration.

</tr>
</tbody>
</table>
The parameter `enabled` specifies whether the Janitor shall be used within A-REX or not. Use the value "0" to disable Janitor. The `uid` and the `gid` are defining which effective user id (uid) and group id (gid) shall be used for the Janitor.† The `registrationdir` describes the directory in which the subdirectories `jobs` and `rtes` will be created. In these directories the states of the jobs and the runtime environments will be stored. The knowledge base of installable packages is specified by the parameter `catalog`. Its value can be any kind of URL pointing to a file written in the Resource Description Framework (RDF) format. The specification of the RDF file will be explained in detail in section 4.3. The parameter `downloaddir` assigns the directory in which the installation files will be saved after they have been downloaded or copied from the repository which was specified by the catalog. The `installationdir` finally specifies the directory into which all packages will be installed and should be available for all computing elements, i.e. by using a shared volume. If the configuration file furthermore contains the `runtimedir` tag within the section `grid-manager`, the Janitor will also create a symbolic link in the `runtimedir` pointing to the configuration script of the installation performed by the Janitor. The tags `jobexpirytime` and `rteexpirytime` are used for an automated cleanup and is defined in seconds. The default value for the `jobexpirytime` is seven days and for the `rteexpirytime` three days. The additional tags `allow_base` `deny_base` `allow_rte` and `deny_rte` are used to include or exclude certain base packages or runtime environments of the catalog. This feature is useful, if the catalog is maintained by a higher organization. The path to the log4perl configuration file is defined by the tag `logconf`. An example how to configure ARC and log4perl is provided in the Listings 2.1 and 2.2.

**Listing 2.1: Example arc.conf settings for janitor.**

```plaintext
#Janitor
[janitor]
enabled = "1"
logconf = "/opt/nordugrid/etc/log.conf"
registrationdir = "/var/spool/nordugrid/janitor"
installationdir = "/var/spool/nordugrid/janitor/runtime"
downloaddir = "/var/spool/nordugrid/janitor/download"
jobexpirytime = "7200"
rteexpirytime = "36"
uid = "root"
gid = "0"
allow_base = "*"
allow_rte = "*"
[catalog]
catalog = "/var/spool/nordugrid/janitor/catalog/knowarc.rdf"
```

It should be noted that the `downloaddir` or the `installationdir` specified in arc.conf could be any directory. Those will not be prepared by the package for the Linux distribution but need be created by the administrator manually after the Janitor has been installed. This also holds for the catalog.

When working with several catalogs, then the multiple catalog lines can be placed into the same arc.conf file. But every must go into its own block as separated with

```
janitor/someName
```

directives.

**Listing 2.2: Example log.conf settings for janitor.**

```plaintext
# Master Loglevel
# [OFF | DEBUG | INFO | WARN | ERROR | FATAL]
log4perl.threshold = OFF

log4perl.rootLogger = WARN, DebugLog, MainLog, ErrorLog
log4perl.appender.DebugLog = Log::Log4perl::Appender::Screen
log4perl.appender.DebugLog.layout = PatternLayout
log4perl.appender.DebugLog.layout.ConversionPattern = [%C] %d %p %m %n

log4perl.appender.MainLog = Log::Log4perl::Appender::File
log4perl.appender.MainLog.Threshold = DEBUG
log4perl.appender.MainLog.filename = "/var/log/janitor.log"

log4perl.appender.MainLog.layout = PatternLayout
log4perl.appender.MainLog.layout.ConversionPattern = [%C] %d %p %m %n

log4perl.appender.ErrorLog = Log::Log4perl::Appender::File
log4perl.appender.ErrorLog.Threshold = ERROR
log4perl.appender.ErrorLog.filename = "/var/log/janitor_error.log"
```

†For the time speaking, you need to have started the ARC services as root to allow the Janitor to change into those IDs.
2.2 Limitations

The Janitor is designed to be used on Linux distributions. Its porting to other platforms has not yet been addressed.

The ARC middleware is not ultimately essential for dynamic Runtime Environments. All the Perl code would be functional with any Grid middleware.
3 Usage

The Janitor can be used either with or without the A-REX service. In case A-REX is used, the invocation of the Janitor will be performed in an automated manner. It is then triggered by incoming jobs that request a particular RTE for their execution. If it is not already installed, but available via the Janitor, then it will be installed without further manual intervention.

3.1 Janitor with A-REX

Runtime Environments can be specified using the supported job description languages. The most representative two common languages shall be explained at this point: xRSL and JSDL. Listing 3.1 shows the xRSL example in which two runtime environments are requested.

```
Listing 3.1: Job submission using the xRSL job description language.
1 #
2 (executable = “run.sh”)
3 (arguments = “weka.classifiers.trees.J48” “-t” “weather.arff”)
4 (inputfiles = (“weather.arff” ””))
5 (“stdout” = “stdout”)
6 (“stderr” = “stderr”)
7 (“gml” = “gml”)
8 (“runtimeenvironment” = “APPS/BIO/WEKA-3.4.10”)
9 (“runtimeenvironment” = “APPS/BIO/WISE-2.4.1-5”)
```

The runtime environment names are composed out a directory name, the package name and the version number.

A comprehensive reference manual of the Extended Resource Specification Language (XRSL) can be found at www.nordugrid.org/documents/xrsl.pdf [?]. Within Listing 3.2 an example using JSDL is provided. The specification of assigning runtime environments in JSDL is currently only defined within the nordugrid_jdsl-arc schema http://svn.nordugrid.org/repos/nordugrid/arc1/trunk/src/services/a-rex/grid-manager/jobdesc/jdsl/jdsl.arc.xsd.

```

```
3.2 Janitor without A-REX

In addition to using the Janitor together with A-REX, the Janitor can also be used as a standalone command line tool. The available commands are listed in table ??.

Table 3.1: Overview about the available commands in Janitor.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>register</td>
<td>Registers a job and a set of runtime environments in the Janitor database. Requires the parameters [JOB-ID] and a list of [RTE]s.</td>
</tr>
<tr>
<td>deploy</td>
<td>Downloads and installs the desired runtime environments. Requires the name of an already registered [JOB-ID].</td>
</tr>
<tr>
<td>remove</td>
<td>Removes the placeholder of the job on the runtime environments. If no more jobs are using the runtime environment and the lifespan of the runtime environment has been expired, the runtime environment can be removed using the sweep command. Requires the [JOB-ID] to be removed.</td>
</tr>
<tr>
<td>sweep</td>
<td>Removes unused runtime environments. No further arguments are required. Using the option --force enforces the removal of all unused runtime environments. Runtime environments having the state FAILED will not be removed.</td>
</tr>
<tr>
<td>setstate</td>
<td>Changes the state of a dynamically installed runtime environment. This might be useful in case a runtime environment with a state FAILED shall be removed (new state might be REMOVAL_PENDING). Requires the argument [STATE] followed by a list of [RTE]s.</td>
</tr>
<tr>
<td>search</td>
<td>Performs a simple search in the catalog and the manually installed runtime environments (runtimedir). Requires no [JOB-ID] nor [RTE]s, but only a list of string to be searched for.</td>
</tr>
<tr>
<td>list</td>
<td>Lists all information about jobs, automatically installed runtime environments and manually installed runtime environments. No additional parameters have to be passed.</td>
</tr>
<tr>
<td>info</td>
<td>Renders information about a job. Requires the parameter [JOB-ID].</td>
</tr>
</tbody>
</table>

Job id: A unique sequence of numbers. Once Janitor registered a job id, it cannot register a second job having the same job id.

Runtime environments: Runtime environments are defined by a continuous string. The name of valid runtime environment names can be investigated using the list or the search commands. They are defined in the catalog or by the directories and scripts of the runtimedir of the grid-manager.
The most important commands for the Janitor are `register`, `deploy` and `remove`. To register a job along with a set of runtime environments in Janitor, the first command `register` followed by a job identifier and a list of runtime environments has to be used. A job is identified by a sequence of numbers. Runtime environments are specified by a string containing the name as it is defined within the Catalog (resp. the runtime directory of the grid-manager). The command `deploy` extracts the necessary dependencies of the desired runtime environments to then download and install the required packages.

In order to remove jobs registered in the Janitor, the command `remove` has to be used. The command only removes the job entry and the lock on the runtime environment. If there are no more locks on the runtime environment it is ok to be deleted also physically from the disk. The demand to pass a job number for the removal of a RTE is irritating at first. This shall prevent the removal of runtime environments that are still being used by jobs in the system. Instead, the janitor is informed about a job’s termination and is requested to remove the assignment of that job to the runtime environment. Only those RTEs with no job-assignment are eligible for being swept. RTEs come with an expiry time or the command may be performed via the command line.

Easy command line examples are provided in Listing 3.3.

Every command has a certain behaviour for its exit status. Table 3.2 lists the possible outcomes.

<table>
<thead>
<tr>
<th>Command</th>
<th>Exit Status 0</th>
<th>Exit Status 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>register</td>
<td>Registration was successful. No noteworthy occurrences.</td>
<td>Registration was successful but some runtime environments aren’t installed yet. Deploy is mandatory.</td>
</tr>
<tr>
<td>deploy</td>
<td>Successfully initialized job.</td>
<td>Can’t provide requested runtime environments.</td>
</tr>
<tr>
<td>remove</td>
<td>Successfully removed job or no such job.</td>
<td>Can’t provide requested runtime environments.</td>
</tr>
<tr>
<td>sweep</td>
<td>Always returns this exit code.</td>
<td></td>
</tr>
<tr>
<td>setstate</td>
<td>Changing the state was successful.</td>
<td>Can not change the state.</td>
</tr>
<tr>
<td>search</td>
<td>Search sucessfully finished.</td>
<td></td>
</tr>
<tr>
<td>list</td>
<td>Successfully retrieved information.</td>
<td></td>
</tr>
<tr>
<td>info</td>
<td>Successfully retrieved job information.</td>
<td>No such job.</td>
</tr>
</tbody>
</table>

**Table 3.2: Possible exit states of Janitor**

# janitor info 1999
```

3.3 Example
4 Maintenance

This chapter explains how to maintain the Catalog and the Janitor itself. It gives detailed instructions how to create new packages for the Janitor. To administrate the catalog, it is strongly recommended (but not ultimately required) to use the ontology editor Protégé, as explained in the next section. In the last section, a typical use case in maintaining the Janitor will be shown.

4.1 Catalog

The Catalog describes runtime environments and is either served through a web server or is distributed together with the Janitor as a regular file. It is specified by a (Resource Description Framework) RDF file assigned to Janitor using the tag `catalog` within the configuration file (see 2.1). The format of the RDF file is defined by an RDF schema file `knowarc.rdfs` which can be found along with an RDF example file `knowarc.rdf` in the Janitor source directory `http://svn.nordugrid.org/repos/nordugrid/arc1/trunk/src/services/janitor/resources/catalog/`.

To edit the catalog, the ontology editor Protégé should be used. Figure 4.1 shows the editor while the MetaPackage `APPS/BIO/JASPAR-CORE-1.0` of the example file has been selected.

On the left side of the editor the class browser is placed. Three main classes are prepared: Metapackage, Note and Package. The Metapackage is a general platform-independent description of a Package. It has one or more instances of the class Package and is described by the subclasses of Note. The class Note has two subclasses: BaseSystem and Tag to describe the Metapackage. The BaseSystem describes the Debian release a Package refers to (i.e. here etch or sid), i.e. the name of a common installation or a virtual image. The class Tag provides small keywords which can be assigned to Metapackages such that they can be found more easily. TarPackage and DebianPackage or currently the only subclasses of Package. They are representing the necessary information (i.e. URL or Packagename) for the installation. In order to have an overview how the classes are interacting with each other the tables 4.1, 4.2, 4.3, 4.4 and 4.5 are pictured.

<table>

</tbody>
</table>

4.2 HTML interface of the catalog

The dynamic Runtime Environments stored in the Catalog are presented on the aforementioned dedicated web page*. This site also links to both the formal Catalog in RDF syntax and its automated transformation to HTML. The latter mimics the traditional site describing Runtime Environments in the Runtime Environment Registry† in order to minimise issues with an eventual transition to the new system. That page collects

descriptions for Runtime Environments to encourage human site administrators to install these. This HTML page listing the manually or automatically installable REs is prepared by the script web/list.pl. This script is meant to be run by a mod_perl-enabled Apache. The script itself does not contribute to the core functionality of the Janitor. In the first lines of the script some variables specific to the site are set. To configure the script these have to be changed [?, p. 9].
4.3 Introducing new packages

This section describes how to add new packages to the Catalog. In the current implementation, only tar-based packages are processed by the Janitor. Within the example they are assigned to be used together with Debian Etch. This limitation is only literal. There is no restriction for newer Debian distributions.

4.3.1 Debian Etch (tar based)

At the time of writing, only the tape archive (tar) file format is accepted for dynamic Runtime Environment installation, a well accepted file format throughout the UNIX community. The concept reflects the traditional manual approach towards RTE in ARC, for which one directory is made available to all compute nodes. This section explains the inner structure of the tar files. Subdirectories are visualised in Figure 4.2.

The tar file contains two directories, named control and data. Software is stored in the latter subdirectory, while the files formally specifying how to deal with such packages are stored in the prior. Upon installation, the content of the data directory is extracted to some directory $\text{BAR}$. After this unpacking of the tar file, the Janitor executes the install script provided in the control directory. It is executed within the working directory $\text{BAR}$. The job of this script is to perform any necessary post-processing. The Janitor stores the file control/remove. It will be executed in the same way as control/install just before the tar-package

</tbody>
</table>
is removed. In most cases control/remove will be empty. Finally, the file control/runtime is sourced multiple times by the Grid Manager’s job-submit script. After installing the package, the Janitor changes all occurrences of %BASEDIR% in the runtime script to $BAR. Once the tar file was prepared, it must its entry to a RTE Catalogue [?, p. 10].

From such Catalogs, the Janitor finds all information to install packages that possibly have never been installed on the site before. The offers of RTEs in a Catalog are cross-checked against the local infrastructure and a subset of the available packages will be accepted as "installable". This list of installable RTEs is forwarded to the grid information system.

### 4.3.2 Automated transformation of install directory to dRTE

The script ‘prepareDRE.pl’ was created to help with the transformation of a readily installed software into a dynamic runtime environment. I also prepares a complete catalog file that can be offered individually or next to other catalogs. See the associated man page prepareDRE(8) for details.

### 4.3.3 Prototypes

In order to have an impression how the tar files are created, several prototypes are provided at [http://dre.knowarc.eu](http://dre.knowarc.eu).

The WEKA package for machine learning [?] and the Java Runtime Environment are available as dynamic Runtime Environments. Further packages for bioinformatics comprise dynamic variants of tools for the analysis of transcription factor binding sites. These are already offered for manual installation via the prior mentioned traditional page representing Runtime Environments for ARC. The corresponding tar file is named somewhat???. The data directory simply contains a ZIP file which needs to be unzipped in the installation directory. For that reason, the control/install script is written as follows:

```bash
#!/bin/sh
set -e # Makes the script to terminate at the first line it fails.

WEKA_ZIP="weka-3-4-8a.zip"
unzip $WEKA_ZIP
rm -f $WEKA_ZIP
```

The runtime script sets the environment variable of the Java Classpath:

```bash
#!/bin/sh

WEKA_JAR="weka-3-4-8a/weka.jar"
case "\$1" in
  0) # Just before job submission
     # none
     ;;
  1) # Just before job execution
     # Initialize the java environment
     CLASSPATH="%BASEDIR%/\$WEKA_JAR:\$CLASSPATH"
     export CLASSPATH
     ;;
  2) # After job termination
     # none
     ;;
  *)
     return 1
     ;;
esac
```

```bash
WEKA_JAR="weka-3-4-8a/weka.jar"
case "\$1" in
  0) # Just before job submission
     # none
     ;;
  1) # Just before job execution
     # Initialize the java environment
     CLASSPATH="%BASEDIR%/\$WEKA_JAR:\$CLASSPATH"
     export CLASSPATH
     ;;
  2) # After job termination
     # none
     ;;
  *)
     return 1
     ;;
```

The WEKA package for machine learning [?] and the Java Runtime Environment are available as dynamic Runtime Environments. Further packages for bioinformatics comprise dynamic variants of tools for the analysis of transcription factor binding sites. These are already offered for manual installation via the prior mentioned traditional page representing Runtime Environments for ARC. The corresponding tar file is named somewhat???. The data directory simply contains a ZIP file which needs to be unzipped in the installation directory. For that reason, the control/install script is written as follows:

```bash
#!/bin/sh
```

```bash
set -e # Makes the script to terminate at the first line it fails.

WEKA_ZIP="weka-3-4-8a.zip"
unzip $WEKA_ZIP
rm -f $WEKA_ZIP
```

The runtime script sets the environment variable of the Java Classpath:

```bash
#!/bin/sh

WEKA_JAR="weka-3-4-8a/weka.jar"
case "\$1" in
  0) # Just before job submission
     # none
     ;;
  1) # Just before job execution
     # Initialize the java environment
     CLASSPATH="%BASEDIR%/\$WEKA_JAR:\$CLASSPATH"
     export CLASSPATH
     ;;
  2) # After job termination
     # none
     ;;
  *)
     return 1
     ;;
```
The remove script, which will be executed right before WEKA is deinstalled, is empty. Janitor will delete the directory, so there is nothing more to be done.

To address the concerns of the physicists using ARC, a dynamic runtime environment for the ATLAS software suite was prepared. It extends prior work on an automated installation that is available at http://guts.uio.no/atlas/12.0.6/. The preparation comprised the following steps:

- The file system path specifications in the automated installation scripts were modified using the Janitor path variables.
- A tarball was prepared containing a directory structure as illustrated in Figure 4.2. The data directory was empty, since the automatic installation script downloads the software from a remote server.
- An entry was added to the Catalog file.

What sets High Energy Physics software apart is it’s sheer size. The package in question takes up more than 5 GB. This was a test illustrating the feasibility of using dynamic REs in High Energy Physics. The application of the dynamic RE for ATLAS needs to wait for the planned web service extension of the Catalog. With such a service, e.g. a software manager of a big experiment will be able to deploy software packages on production sites simply by creating a tarball and adding an entry to the Catalog.
4 Maintenance
5 Technical Motivation and Concepts

The current implementation, using the rather advanced concepts of the semantic web, may seem unexpected. They were chosen since they are expected to scale with all the extra demands foreseen for the Janitor.

5.1 Implementation

5.1.1 Choice of Perl

The main language for the implementation of the functionality of the dRTE’s functionality is Perl. And it is solely required (exceptions are the integration with the Grid Manager and the Web server) for the Janitor. The language was perceived a side-issue, the complexity of the data expected was of major concern.

5.1.2 Modular structure

In the pre-web-service implementation the Catalog remains a static web page. The Perl code is split into multiple modules as depicted in Figure ???. The modules can be separated into two functional groups. One addresses the retrieval of information from the Catalog’s RDF file in the left major branch of the figure. The other addresses the process of fetching and installing the packages.
Figure 5.1: Modules of the Janitor and their dependencies
In order to get a more detailed view on the full functionality of the envisioned system it is suggested to consult the Design Document*.

5.2 Concepts

In the following, some paragraphs fail render it difficult to clearly distinguish between conceptional truths and the state of the current implementation. Please read carefully.

5.2.1 States of runtime environments

A major motivation for the managed, manual initiation of dynamic RE installation is the subsequent manual verification of the installed packages - prior to their use in production. It would be nice to see the Janitor and/or the Catalog prepare for reviews by selected users. This has not yet been implemented.

With an automation of the installation, the verification of that process shall be performed externally to that process. At this time, only the automation of the installation has been implemented. To reflect the progress the external verification has made, REs are said to be in states. The current implementation lists installable REs aside the installed REs in the grid information system, in order to stimulate grid clients to submit packages. The here described states will be represented to the clients in upcoming developments.

These states are specific for every compute element (CE) and communicated between the Janitor and the Execution Service. Table 5.1 shows all possible states, while Figure 5.5 displays the transitions between the states that a Runtime Environment may be in during its life time at a particular CE.

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNAVAILABLE</td>
<td>The RE is not available for the BaseSystem (see ??) the site uses.</td>
</tr>
<tr>
<td>INSTALLABLE</td>
<td>The RE is available for the BaseSystem the site uses and it will be automatically installed once a job requests it.</td>
</tr>
<tr>
<td>INSTALLING/a</td>
<td>A job requested the RE and it is currently being installed</td>
</tr>
<tr>
<td>INSTALLING/m</td>
<td>The RE-administrator requested the installation of the RE. Its currently being installed.</td>
</tr>
<tr>
<td>FAILED</td>
<td>The installation process failed.</td>
</tr>
<tr>
<td>INSTALLED/a</td>
<td>The RE is installed dynamically.</td>
</tr>
<tr>
<td>INSTALLED/m</td>
<td>The RE ist installed manually by the RE-administrator</td>
</tr>
<tr>
<td>BROKEN/m</td>
<td>The RE is installed but failed tests of the RE-administrator</td>
</tr>
<tr>
<td>VALIDATED/m</td>
<td>The RE is installed and successfully passed the tests of the RE-administrator</td>
</tr>
<tr>
<td>REMOVAL PENDING</td>
<td>The RE is still installed but will be removed as soon as possible. It is not available to new jobs.</td>
</tr>
<tr>
<td>REMOVING</td>
<td>The RE is currently being removed.</td>
</tr>
<tr>
<td>INSTALLED/s</td>
<td>The RE was installed in the traditional way by the site administrator.</td>
</tr>
<tr>
<td>BROKEN/s</td>
<td>The RE was installed in the traditional way and failed validation by the RE-administrator,</td>
</tr>
<tr>
<td>VALIDATED/s</td>
<td>The RE was installed in the traditional way and was successfully verified.</td>
</tr>
</tbody>
</table>

Table 5.1: States a Runtime Environment can possibly be in.

The manually induced transitions are marked in red, he automated transitions in black. A transition between states can be induced automatically (i.e. by the advent of a job requesting a particular dynamic RE) or manually by the site’s supervisor or an individual with respective rights to use the Janitor’s web service.

5 Technical Motivation and Concepts

Figure 5.2: Relationships between the possible states of Runtime Environments. Red arcs represent human interaction. The distinction between /a, /m and /s states does not need to be visible for all clients.

5.2.2 Subset of that functionality as implemented today

Upon presentation of a the package name to a Catalog, from which details about the package are retrieved, a CE may classify a package to be INSTALLABLE if all the dependencies are installable or already INSTALLED. The installation can be performed manually (INSTALLING/m) or in an automated fashion (.../a). Should the installation process return an error, then the installation has FAILED. Once the installation succeeded, the installed package is validated for its correctness. Should that process fail, then the package’s state it is said to be BROKEN.

Automatically installed packages can be removed by the automatism. A manually installed package or one that has failed to be installed, can only be removed upon manual induction. The .../s states represent those Runtime Environments that are installed in the original manual way of RE installation in ARC 0.6.

5.3 Job states

The Janitor manages the states that the runtime environments at a particular compute element are in. However, it is also most important for the Janitor to be aware of the jobs that depend on the installation of a RE. REs still in use should not be removed until the respective job has completed its computations. The installation or removal of REs by the Janitor is perceived as a mere consequence of jobs demanding a RE or not, thus, the communication between the job-manager AREX and the Janitor will be performed on that ‘job level’.

The Janitor has two states for jobs: PREPARED and INITIALIZED. After a job has been successfully registered in the Janitor, its state will be set to PREPARED. Invalid jobs are not cached. After the Janitor is requested to deploy the runtime environment, the state of the job will change to INITIALIZED. If an unforeseen exception occurs during that process, the Janitor will drop the job from its database and set the affected runtime environments to the state FAILED.
5.4 Integration with AREX

The integration into AREX is not completed yet!
Thus, there will be bigger changes here in this section...

```
5.5 WebService Interface

5.5.1 What happens during installation

Register
1. Look up Catalog and find corresponding runtime environments.
2. Check if dependencies are available (installed or installable)
3. Store job in registrationdir

Deploy
1. Load job out of registrationdir
2. Look up Catalog and find corresponding runtime environments.
3. Check if dependencies are available (installed or installable)
4. Download RTEs into the downloaddir
5. [ to be continued or skipped ]

5.5.2 Security Consideration

Security is a major concern for grid systems. Any additional feature and especially an automatic software installation inherently introduces security threats. This section addresses those and describes the available solutions to limit security risks.

In the current installation, every user authorised to execute a job is also authorised to install a REs. Restrictions are only imposed on the set of dynamic REs that are available for installation. Restrictions are imposed by the site administrators on the descriptions that are given by the Catalog that is offering the package. These descriptions may explicitly mention dynamic REs' names, e.g. a regular expression on these, or refer to tags of packages that categorise these. However, the core of these controls lies with the maintainers of the Catalog, who needs to be trusted.

All dynamic REs are installed in separate directories. The provisioning of disk space is the duty of the site administrator. In the current implementation, the installation is completely transparent to the user:

- Dynamic REs are not distinguished between installed and installable in the information system.
- No status information is given at the time a dynamic RE is installed.

Malevolent regular users with respective training in using system exploits to gain root access are likely to find security holes by regularly submitted scripts. The authentication and authentification of users, together with respective logging, is the major defense against such attacks. What is consequently left to be protected against are unwanted side-effects by the installation of software.

The worst case scenario would be the installation of a RE that overwrites system files. With the current implementation, which is based solely on tar files, this is barely possible, unless such is performed by the install scripts that accompany the tar files. However, hereto the installation would have to be performed by a user with system privileges, for which there is no technical requirement.

The installation of packages from the Debian distribution (or other packages of mainstream Linux distributions) is sought to reduce the complexity and burden in the maintenance for dynamic REs. In the current implementation, Debian packages may be installed only by their transformation into tar files. With the advent of the interface for the virtualisation of the grid infrastructure, it is anticipated to work with native packages of the Debian Linux distribution. The reuse of packages that passed many eyeballs - as it is the case with packages from major Linux distribution - security is further increased or becomes as high as with the operating system underneath virtual clients.
Summarising, there is general concern about the security of grid computing. Dynamic REs introduce new dangers since a manual control at the grid site is substituted by a remote process that is out the direct supervision of a local site administrator. The signing of packages by known and directly or indirectly trusted developers is a good indicator that no malevolent individuals have tampered with the binary. The site administrators can limit the sources of packages and specify packages that are eligible or excluded from installations.
6 Outlook

6.1 Representation of dynamic RTEs in the information model

Dynamic RTEs require an extended representation in the information model. The Application Software description should be able to distinguish installed RTEs from installable RTEs, potentially offer description of extended RTE state-like information. This work is planned to be carried out as part of the Glue-2.0 effort of OGF*.

6.2 Integration with Workflow Management

Future development of ARC aims at integrating grid computing with workflow tools for the web services that have a growing user base in bioinformatics. The challenge is to prepare RTEs for programs or databases and to offer such concisely to users of the workflow environments. In the bioinformatics community, such are today offered as web services. This anticipated development instead fosters the dynamic installation on the grid whenever appropriate to allow for special computational demands in high-throughput analyses. Conversely, because of the increased complexity of workflows with respect to the already today not manually manageable number of RTEs, without an automatism for the automated installation of software packages on the grid, the use of workflows in grid computing seems mute.

6.3 Implementation of a Catalog service

A Catalog service is planed to be implemented on top of the ARC HED component. This service will render the currently used locally accessible RDF file externally accessible. Selected users are then allowed to remotely add/edit/remove REs to/from it. The Janitor will access the content of the Catalog through a well-defined Web Service interface.

6.4 Integration with the Virtualization work

The RDF schema nicely prepares for the upcoming virtualisation of worker nodes. Hereto, the BaseSystem indicates a virtual image to which further packages, the dynamic REs, would then be added. How exactly the dynamics are integrated will depend on how dynamic the virtualisation of the nodes is. In the simplest scenario, a worker node’s CPU will only be occupied by a single virtual machine and that will not be changed. In this case, there is no difference to the setup of the Janitor with today’s static setups.

However, if the BaseSystems can be substituted dynamically, then a RE can possibly be offered via multiple BaseSystems. The RDF Schema describes BaseSystems as separate instances and as such differs from the current RE registry. Heuristics that prefer one BaseSystem for another can make direct use of the data that is presented in the schema. The integration of packages from Linux distributions in the description of REs is essential to have a means to decide for the equivalence of manual additions and the functionality that comes with BaseSystem.
